

An alternate mathematical model for single-wall carbon nanotubes

Nicolae Cotfas

Bucharest, Romania*

Abstract

The positions of atoms forming a carbon nanotube are usually described by using a system of generators of the symmetry group. Each atomic position corresponds to an element of the set $\mathbb{Z} \times \{0, 1, \dots, n\} \times \{0, 1\}$, where n is a natural number depending on the considered nanotube. We obtain an alternate rather different description by starting from a description of the honeycomb lattice in terms of Miller indices. In our mathematical model which is a factor space defined by an equivalence relation in the set $\{(v_0, v_1, v_2) \in \mathbb{Z}^3 \mid v_0 + v_1 + v_2 \in \{0, 1\}\}$ the neighbours of an atomic position can be described in a simpler way, and the mathematical objects with geometric or physical significance have a simpler and more symmetric form.

Key words: Single-wall carbon nanotube, honeycomb lattice, energy levels
PACS: 61.46.+w, 73.63.Fg

1 Introduction

The carbon nanotubes, discovered by Iijima in 1991, have several remarkable physical properties (geometry-dependent electronic transport from metallic to semiconducting with narrow and moderate band gaps, record-high elastic modulus, light weight) and many potential applications (molecular electronic devices, fiber reinforcement technologies, flat displays, carbon-based nanotips). Extensive experimental and theoretical investigations have been carried out on the mechanical and electronic properties of these novel fibers.

The structure of a single-wall carbon nanotube observed by scanning tunneling microscopy [14] can be visualized as the structure obtained by rolling a

Email address: ncotfas@yahoo.com (Nicolae Cotfas).

graphene sheet such that the endpoints of a translation vector are folded one onto the other. The geometric and physical properties of the obtained carbon nanotube depend on this vector, called the *chirality* of the tubule. The position of the atoms forming a carbon nanotube are usually described by using a system of generators of the corresponding symmetry group. Our purpose is to present an alternate mathematical model obtained by starting from a three-axes description (that is, a description in terms of Miller indices [13]) of the honeycomb lattice.

2 Honeycomb lattice in a three-axes description

The vectors $e_0 = (2/\sqrt{6}, 0)$, $e_1 = (-1/\sqrt{6}, 1/\sqrt{2})$, $e_2 = (-1/\sqrt{6}, -1/\sqrt{2})$ corresponding to the vertices of an equilateral triangle form a system of coherent vectors [2], that is, for any $v = (v_x, v_y)$, $u = (u_x, u_y) \in \mathbb{R}^2$ we have

$$v = \sum_{i=0}^2 \langle v, e_i \rangle e_i \quad \langle v, u \rangle = \sum_{i=0}^2 \langle v, e_i \rangle \langle u, e_i \rangle \quad ||v||^2 = \sum_{i=0}^2 \langle v, e_i \rangle^2 \quad (1)$$

where $\langle, \rangle$ is the usual scalar product. The numbers $\tilde{v}_0 = \langle v, e_0 \rangle$, $\tilde{v}_1 = \langle v, e_1 \rangle$, $\tilde{v}_2 = \langle v, e_2 \rangle$ satisfy the relation $\tilde{v}_0 + \tilde{v}_1 + \tilde{v}_2 = 0$ and can be regarded as the *canonical coordinates* of v with respect to the system of vectors $\{e_0, e_1, e_2\}$. The space

$$\mathcal{E} = \{(u_0, u_1, u_2) \in \mathbb{R}^3 \mid u_0 + u_1 + u_2 = 0\} \quad (2)$$

becomes in this way a mathematical model for the geometric plane. The correspondence between this description and the usual one is given by the isometry

$$\mathcal{I} : \mathbb{R}^2 \longrightarrow \mathcal{E} \quad \mathcal{I}v = (\tilde{v}_0, \tilde{v}_1, \tilde{v}_2) \quad \mathcal{I}^{-1}(u_0, u_1, u_2) = \sum_{i=0}^2 u_i e_i. \quad (3)$$

The representation of a vector $v \in \mathbb{R}^2$ as a linear combination of e_0 , e_1 , e_2 is not unique. More exactly, we have

$$v = \sum_{i=0}^2 v_i e_i \quad \Longleftrightarrow \quad (v_0, v_1, v_2) \in \{(\tilde{v}_0 + \alpha, \tilde{v}_1 + \alpha, \tilde{v}_2 + \alpha) \mid \alpha \in \mathbb{R}\}.$$

Fig. 1. The honeycomb lattice and the partition defined by a vector $c \in \mathcal{T}$.

For each $v \in \mathbb{R}^2$ we denote by (v_0, v_1, v_2) (or simply by v) an element of $\mathbb{R}^3$ such that $v = v_0 e_0 + v_1 e_1 + v_2 e_2$. One can verify by direct computation that

$$\langle u, v \rangle = \sum_{i=0}^2 \tilde{u}_i \tilde{v}_i = \sum_{i=0}^2 \tilde{u}_i v_i = \sum_{i=0}^2 u_i \tilde{v}_i \quad (4)$$

for any $u, v \in \mathbb{R}^2$.

The points of the plane $\mathbb{R}^2$ corresponding to the elements of the set

$$\mathcal{L} = \left\{ v = (v_0, v_1, v_2) \in \mathbb{Z}^3 \mid v_0 + v_1 + v_2 \in \{0, 1\} \right\} \quad (5)$$

are distinct and form [3] the *honeycomb lattice*

$$\Lambda = \left\{ \sum_{i=0}^2 v_i e_i \mid v = (v_0, v_1, v_2) \in \mathcal{L} \right\}. \quad (6)$$

The bijection $\mathcal{L} \longrightarrow \Lambda : v \mapsto \sum_{i=0}^2 v_i e_i$ allows us to describe Λ by using $\mathcal{L}$.

The *nearest neighbours* of v are

$$v^0 = (v_0 + \nu(v), v_1, v_2) \quad v^1 = (v_0, v_1 + \nu(v), v_2) \quad v^2 = (v_0, v_1, v_2 + \nu(v))$$

where $\nu(v) = (-1)^{v_0+v_1+v_2}$. The six points $v^{ij} = (v^i)^j$ corresponding to $i \neq j$ are the *next-to-nearest neighbours* of v , and one can remark that $v^{ii} = v$, $v^{ijl} = v^{lji}$, for any $i, j, l \in \{0, 1, 2\}$. The mapping [4]

$$d : \mathcal{L} \times \mathcal{L} \longrightarrow \mathbb{N} \quad d(v, u) = |v_0 - u_0| + |v_1 - u_1| + |v_2 - u_2| \quad (7)$$

is a distance on $\mathcal{L}$, and a point u is a *neighbour of order l* of v if $d(v, u) = l$.

We have $\mathcal{L} = \mathcal{T} \cup (\mathcal{T} + \vartheta)$, where $\vartheta = (1, 0, 0)$ and

$$\mathcal{T} = \{v = (v_0, v_1, v_2) \in \mathbb{Z}^3 \mid v_0 + v_1 + v_2 = 0\} = \mathcal{E} \cap \mathbb{Z}^3. \quad (8)$$

The symmetry group G of the honeycomb lattice coincides with the group of all the isometries of the metric space $(\mathcal{L}, d)$, and is generated by the transformations [4]

$$\begin{aligned} \sigma : \mathcal{L} &\longrightarrow \mathcal{L} & \sigma(v_0, v_1, v_2) &= (v_1, v_2, v_0) \\ \varrho : \mathcal{L} &\longrightarrow \mathcal{L} & \varrho(v_0, v_1, v_2) &= (v_0, v_2, v_1) \\ \tau : \mathcal{L} &\longrightarrow \mathcal{L} & \tau(v_0, v_1, v_2) &= -(v_0, v_1, v_2) + \vartheta. \end{aligned} \quad (9)$$

The group G contains the subgroup of translations (also denoted by $\mathcal{T}$)

$$\{\mathcal{L} \longrightarrow \mathcal{L} : v \mapsto v + u \mid u \in \mathcal{T}\}$$

generated by $\sigma^2\tau\sigma\tau$ and $\sigma\tau\sigma^2\tau$

$$\begin{aligned} \sigma^2\tau\sigma\tau(v_0, v_1, v_2) &= (v_0, v_1, v_2) + (-1, 1, 0) \\ \sigma\tau\sigma^2\tau(v_0, v_1, v_2) &= (v_0, v_1, v_2) + (-1, 0, 1). \end{aligned} \quad (10)$$

It is known [12] that the C-C bond length in the case of a graphene sheet is 1.44 Å. If we use the honeycomb lattice $\mathcal{L}$ as a mathematical model for a graphene sheet then we have to multiply the position vectors of the points of the lattice by the constant $a = 1.44\sqrt{6}/2$ in order to get their lengths in Å.

Consider the Hilbert space $(l^2(\mathcal{L}), \langle \cdot, \cdot \rangle)$, where

$$\begin{aligned} l^2(\mathcal{L}) &= \left\{ \psi : \mathcal{L} \longrightarrow \mathbb{C} \mid \sum_{v \in \mathcal{L}} |\psi(v)|^2 < \infty \right\} \\ \langle \psi_1, \psi_2 \rangle &= \sum_{v \in \mathcal{L}} \overline{\psi_1(v)} \psi_2(v) \end{aligned} \quad (11)$$

and the unitary representation of G in $l^2(\mathcal{L})$ defined by

$$g : l^2(\mathcal{L}) \longrightarrow l^2(\mathcal{L}) \quad (g\psi)(v) = \psi(g^{-1}v). \quad (12)$$

Let ε be a real number, and $\gamma_0, \gamma_1, \gamma_2$ be three complex numbers. The linear operator

$$H : l^2(\mathcal{L}) \longrightarrow l^2(\mathcal{L}) \quad (H\psi)(v) = \varepsilon\psi(v) + \sum_{j=0}^2 \gamma(v, v^j) \psi(v^j) \quad (13)$$

where

$$\gamma(v, v^j) = \begin{cases} \gamma_j & \text{if } \nu(v) = 1 \\ \bar{\gamma}_j & \text{if } \nu(v) = -1 \end{cases} \quad (14)$$

is a self-adjoint operator

$$\begin{aligned} \langle H\psi_1, \psi_2 \rangle &= \varepsilon \sum_{v \in \mathcal{L}} \bar{\psi}_1(v) \psi_2(v) + \sum_{j=0}^2 \sum_{v \in \mathcal{L}} \bar{\gamma}(v, v^j) \bar{\psi}_1(v^j) \psi_2(v) \\ &= \varepsilon \sum_{v \in \mathcal{L}} \bar{\psi}_1(v) \psi_2(v) + \sum_{j=0}^2 \sum_{v \in \mathcal{L}} \gamma(v, v^j) \bar{\psi}_1(v) \psi_2(v^j) = \langle \psi_1, H\psi_2 \rangle. \end{aligned}$$

The Hamiltonian used in the tight-binding description of π bands in 2D graphite, with only first-neighbour $C - C$ interaction, has the form (13).

Theorem 1. *For any $k = (k_0, k_1, k_2) \in \mathcal{E}$ the real numbers*

$$E_{\pm}(k) = \varepsilon \pm |\gamma_0 e^{ik_0 a} + \gamma_1 e^{ik_1 a} + \gamma_2 e^{ik_2 a}| \quad (15)$$

belong to the spectrum of H .

Proof. The function

$$\varphi : \mathcal{L} \longrightarrow \mathbb{C} \quad \varphi(v) = \begin{cases} \alpha & \text{for } v \in \mathcal{T} \\ \beta & \text{for } v \in \mathcal{T} + \vartheta \end{cases}$$

where α, β are two constants, is invariant under any translation $u \in \mathcal{T}$

$$\varphi(v + u) = \varphi(v) \quad \text{for all } v \in \mathcal{L}.$$

The Bloch type function

$$\psi_k : \mathcal{L} \longrightarrow \mathbb{C} \quad \psi_k(v) = \varphi(v) e^{i\langle k, v \rangle a} \quad (16)$$

Fig. 2. The first Brillouin zone $\mathcal{B}$ (left) and the set $\mathcal{B}_c$ in case $n = 4$ (right).

belonging to an extension of the space $l^2(\mathcal{L})$ satisfies the relation $H\psi_k = E\psi_k$ if and only if (α, β) is a solution of the system of equations

$$\begin{cases} \varepsilon\alpha + (\gamma_0 e^{ik_0 a} + \gamma_1 e^{ik_1 a} + \gamma_2 e^{ik_2 a})\beta = E\alpha \\ (\bar{\gamma}_0 e^{-ik_0 a} + \bar{\gamma}_1 e^{-ik_1 a} + \bar{\gamma}_2 e^{-ik_2 a})\alpha + \varepsilon\beta = E\beta. \end{cases}$$

This system has non-trivial solutions if and only if

$$\begin{vmatrix} \varepsilon - E & \gamma_0 e^{ik_0 a} + \gamma_1 e^{ik_1 a} + \gamma_2 e^{ik_2 a} \\ \bar{\gamma}_0 e^{-ik_0 a} + \bar{\gamma}_1 e^{-ik_1 a} + \bar{\gamma}_2 e^{-ik_2 a} & \varepsilon - E \end{vmatrix} = 0$$

that is, if and only if E is one of the numbers $E_{\pm}(k)$. $\blacksquare$

The origin on the energy axis is usually chosen such that $\varepsilon = 0$. If $\gamma_0 = \gamma_1 = \gamma_2 = \gamma$ is a real positive number then H is a G -invariant self-adjoint operator and its spectrum contains for each $k \in \mathcal{E}$ the numbers $\pm E(k)$, where

$$\begin{aligned} E(k) &= \gamma |e^{ik_0 a} + e^{ik_1 a} + e^{ik_2 a}| \\ &= \gamma \sqrt{3 + 2 \cos(k_0 - k_1)a + 2 \cos(k_1 - k_2)a + 2 \cos(k_2 - k_0)a}. \end{aligned} \quad (17)$$

The relation (17) allows us to extend the function $E : \mathcal{E} \rightarrow \mathbb{R}$ to a periodic function $E : \mathbb{R}^3 \rightarrow \mathbb{R}$

$$\begin{aligned} E(k_0, k_1, k_2) &= E\left(k_0 + \frac{2\pi}{a}, k_1, k_2\right) \\ &= E\left(k_0, k_1 + \frac{2\pi}{a}, k_2\right) = E\left(k_0, k_1, k_2 + \frac{2\pi}{a}\right) \end{aligned} \quad (18)$$

with the property

$$E(k_0, k_1, k_2) = E(k_0 + \alpha, k_1 + \alpha, k_2 + \alpha) \quad \text{for all } \alpha \in \mathbb{R}.$$

The corresponding first Brillouin zone is the hexagonal set (figure 2)

$$\mathcal{B} = \left\{ (k_0, k_1, k_2) \in \mathcal{E} \mid -\frac{2\pi}{3a} \leq k_i \leq \frac{2\pi}{3a} \right\} \quad (19)$$

(certain points lying on the frontier of $\mathcal{B}$ are equivalent).

The intervals $[-3\gamma, 0] = \{-E(k) \mid k \in \mathcal{B}\}$ and $[0, 3\gamma] = \{E(k) \mid k \in \mathcal{B}\}$ correspond to the valence π and the conduction π^* energy bands, respectively. The graphene sheet is a conductor since the gap between these bands is null.

Since $E(k)$ can be written as

$$E(k) = \gamma \sqrt{(\cos k_0 a + \cos k_1 a + \cos k_2 a)^2 + (\sin k_0 a + \sin k_1 a + \sin k_2 a)^2}$$

we have $E(k) \geq 0$, and the only points of $\mathcal{B}$ with $E(k) = 0$ are

$$\pm \left(\frac{2\pi}{3a}, -\frac{2\pi}{3a}, 0 \right), \pm \left(\frac{2\pi}{3a}, 0, -\frac{2\pi}{3a} \right), \pm \left(0, \frac{2\pi}{3a}, -\frac{2\pi}{3a} \right) \quad (20)$$

that is, the vertices of the Brillouin zone (usually denoted by K) [10].

It is known that the Fermi level for a graphene sheet occurs at the K points. The function $E : \mathbb{R}^3 \longrightarrow \mathbb{R}$ is not differentiable at these points. We have, for example,

$$\begin{aligned} \lim_{k_0 \rightarrow \frac{2\pi}{3a}} \frac{E(k_0, -\frac{2\pi}{3a}, 0) - 0}{k_0 - \frac{2\pi}{3a}} &= \gamma \lim_{k_0 \rightarrow \frac{2\pi}{3a}} \frac{\sqrt{2 - 2 \cos(k_0 - \frac{2\pi}{3a})}}{k_0 - \frac{2\pi}{3a}} \\ &= 2\gamma \lim_{k_0 \rightarrow \frac{2\pi}{3a}} \frac{\left| \sin \frac{k_0 - (2\pi/3a)}{2} \right|}{k_0 - \frac{2\pi}{3a}} \end{aligned} \quad (21)$$

whence

$$\begin{aligned} \lim_{\substack{k_0 \rightarrow 2\pi/3a \\ k_0 > 2\pi/3a}} \frac{E(k_0, -\frac{2\pi}{3a}, 0) - 0}{k_0 - \frac{2\pi}{3a}} &= \gamma \\ \lim_{\substack{k_0 \rightarrow 2\pi/3a \\ k_0 < 2\pi/3a}} \frac{E(k_0, -\frac{2\pi}{3a}, 0) - 0}{k_0 - \frac{2\pi}{3a}} &= -\gamma. \end{aligned}$$

The function $E : \mathbb{R}^3 \longrightarrow \mathbb{R}$ is differentiable at any point k with $E(k) \neq 0$, and

$$\frac{\partial E}{\partial k_0}(k) = \gamma \frac{-a \sin(k_0 - k_1)a + a \sin(k_2 - k_0)a}{\sqrt{3 + 2 \cos(k_0 - k_1)a + 2 \cos(k_1 - k_2)a + 2 \cos(k_2 - k_0)a}} \quad (22)$$

etc. The stationary points lying in the Brillouin zone $\mathcal{B}$ are

$$(0, 0, 0), \pm \left(\frac{2\pi}{3a}, -\frac{\pi}{3a}, -\frac{\pi}{3a} \right), \pm \left(-\frac{\pi}{3a}, \frac{2\pi}{3a}, -\frac{\pi}{3a} \right), \pm \left(-\frac{\pi}{3a}, -\frac{\pi}{3a}, \frac{2\pi}{3a} \right)$$

that is, the center (a maximum point, denoted by Γ) and the middle of the edges of the Brillouin zone (saddle points, denoted by M).

3 Chiral single-wall carbon nanotubes

A single-wall carbon nanotube can be visualised as the structure obtained by rolling a graphene sheet such that the endpoints O and A of a translation vector $\vec{OA}$ are folded one onto the other (figure 1). The geometric and physical properties of the obtained nanotube depend on this vector, called the *chirality* of the tubule and represented in our approach by an element $c \in \mathcal{T}$. Without loss of generality, we can restrict us to the tubules with $c_0 > c_1 \geq c_2$. In the case $c_1 = c_2$ we have an *armchair* tubule, and in the case $c_1 = 0$ a *zig-zag* tubule. The nanotubes with $0 \neq c_1 \neq c_2$ are called *chiral nanotubes*. The diameter of the nanotube of chirality c is $\|c\|a/\pi$.

After the graphene sheet rolling, the points $\dots, v-2c, v-c, v, v+c, v+2c, \dots$ are folded one onto the other, for any $v = (v_0, v_1, v_2) \in \mathcal{L}$. Thus, each point of the set

$$[v_0, v_1, v_2] = v + \mathbb{Z}c = \{ (v_0 + jc_0, v_1 + jc_1, v_2 + jc_2) \mid j \in \mathbb{Z} \} \quad (23)$$

describes the same point of the carbon nanotube of chirality c . Each rational number is a class of equivalent fractions, called its representatives. In a similar way, for each point of a carbon nanotube we have an infinite number of possibilities to describe it in our model. A mathematical expression containing the coordinates of a point is well-defined only if it does not depend on the representative we choose. We describe the atomic positions on a carbon nanotube by using the subset

$$\mathcal{L}_c = \left\{ [v_0, v_1, v_2] \in \mathbb{Z}^3/(\mathbb{Z}c) \mid v_0 + v_1 + v_2 \in \{0; 1\} \right\}. \quad (24)$$

of the factor space

$$\mathbb{Z}^3/(\mathbb{Z}c) = \{ [v] = (v_0, v_1, v_2) + \mathbb{Z}c \mid v_0, v_1, v_2 \in \mathbb{Z} \} \quad (25)$$

as a mathematical model. One can remark that $\mathcal{L}_c$ is well defined since the condition $v_0 + v_1 + v_2 \in \{0; 1\}$ we impose to $[v_0, v_1, v_2]$ does not depend on the

representative we choose. Indeed, $(v_0 + jc_0) + (v_1 + jc_1) + (v_2 + jc_2) = v_0 + v_1 + v_2$, for all $j \in \mathbb{Z}$.

Each point $[v] \in \mathcal{L}_c$ has three *nearest neighbours*, namely, $[v^0]$, $[v^1]$, $[v^2]$, and six *next-to-nearest neighbours*, namely, $[v^{01}]$, $[v^{10}]$, $[v^{12}]$, $[v^{21}]$, $[v^{20}]$, $[v^{02}]$.

A symmetry transformation of the honeycomb lattice $\mathcal{L} \longrightarrow \mathcal{L} : v \mapsto gv$ defines the *symmetry transformation* $\mathcal{L}_c \longrightarrow \mathcal{L}_c : [v] \mapsto [gv]$ of the carbon nanotube $\mathcal{L}_c$ if

$$[v] = [u] \implies [gv] = [gu]$$

that is, if

$$v - u \in \mathbb{Z}c \implies gv - gu \in \mathbb{Z}c.$$

Theorem 2. *The transformations*

$$\begin{aligned} g_w : \mathcal{L}_c &\longrightarrow \mathcal{L}_c & g_w[v] &= [v + w] \\ \tau : \mathcal{L}_c &\longrightarrow \mathcal{L}_c & \tau[v] &= [-v + \vartheta] \end{aligned} \tag{26}$$

are symmetry transformation of $\mathcal{L}_c$ for all $w \in \mathcal{T}$.

Proof. We have $v - u \in \mathbb{Z}c \implies (v + w) - (u + w) = v - u \in \mathbb{Z}c$, and $v - u \in \mathbb{Z}c \implies (-v + \vartheta) - (-u + \vartheta) = u - v \in \mathbb{Z}c$. ■

Let $n = \gcd\{c_0, c_1, c_2\}$ be the greatest common divisor of c_0, c_1, c_2 , and let $c = nc'$, that is, $c'_0 = c_0/n$, $c'_1 = c_1/n$ and $c'_2 = c_2/n$. The transformation $g_{c'}$ represents a rotation of angle $2\pi/n$ of the nanotube with respect to its axis. Since $(c_1 - c_2)c_0 + (c_2 - c_0)c_1 + (c_0 - c_1)c_2 = 0$, the vector $w = (c_1 - c_2, c_2 - c_0, c_0 - c_1)$ is orthogonal to c , and the corresponding transformation g_w is a pure translation, that is, a translation in the direction of the nanotube symmetry axis. The vector $b = (1/\mathcal{R})(c_1 - c_2, c_2 - c_0, c_0 - c_1)$, where

$$\mathcal{R} = \gcd\{c_1 - c_2, c_2 - c_0, c_0 - c_1\} = \begin{cases} n & \text{if } c'_1 - c'_2 \notin 3\mathbb{Z} \\ 3n & \text{if } c'_1 - c'_2 \in 3\mathbb{Z} \end{cases} \tag{27}$$

defines the shortest pure translation of $\mathcal{L}_c$.

From $c_0 + c_1 + c_2 = 0$ we get $(c_1 - c_2)^2 + (c_2 - c_0)^2 + (c_0 - c_1)^2 = 3(c_0^2 + c_1^2 + c_2^2)$, that is, $\mathcal{R}^2||b||^2 = 3||c||^2$, whence

$$q = \frac{1}{\mathcal{R}}(c_0^2 + c_1^2 + c_2^2) \in n\mathbb{Z}. \tag{28}$$

For any $w \in \mathcal{T}$ the projections of w on c and b can be written as

$$\frac{\langle w, c \rangle}{||c||^2} c = \left(w_1 \frac{c_1 - c_0}{\mathcal{R}} + w_2 \frac{c_2 - c_0}{\mathcal{R}} \right) \frac{c}{q} \quad \frac{\langle w, b \rangle}{||b||^2} b = \left(w_1 \frac{c_2}{n} - w_2 \frac{c_1}{n} \right) \frac{b}{q'}$$

where $q' = q/n$. It is well-known that in the case of two integer numbers $\eta, \mu \in \mathbb{Z}$ with $\gcd\{\eta, \mu\} = 1$ there exist $\alpha, \beta \in \mathbb{Z}$ with $\alpha\eta + \beta\mu = 1$. Since $\gcd\{(c_1 - c_0)/\mathcal{R}, (c_2 - c_0)/\mathcal{R}\} = 1$ and $\gcd\{c_2/n, c_1/n\} = 1$ it follows that the projection of $\mathcal{T}$ on c is $\mathbb{Z}c/q$ and the projection of $\mathcal{T}$ on b is $\mathbb{Z}b/q'$. Let $\omega \in \mathcal{T}$ be the shortest vector with

$$\frac{\langle \omega, b \rangle}{||b||^2} b = \frac{b}{q'}. \quad (29)$$

If $\mathcal{L}_c$ is a chiral nanotube then its symmetry group G_c is generated by the transformations $g_{c'}$, g_ω and τ (additional symmetry operations, namely, mirror and glide planes occur only in the case of armchair and zig-zag nanotubes). More than that, for any $[v] \in \mathcal{L}_c$ there exist $s \in \mathbb{Z}$, $m \in \{0, 1, \dots, n-1\}$ and $p \in \{0, 1\}$ uniquely determined such that

$$[v] = \tau^p g_\omega^s g_{c'}^m [0, 0, 0]. \quad (30)$$

The usual description of the atomic positions of the atoms forming a carbon nanotube [15,16] is based on this remark, and the set

$$\{(s, m, p) \mid s \in \mathbb{Z}, m \in \{0, 1, \dots, n-1\}, p \in \{0, 1\}\} \quad (31)$$

is used as a mathematical model.

The subgroup $\tilde{G}_c$ of G_c generated by $g_{c'}$ and g_ω is a commutative index-two subgroup, and $g_{c'}^n = I$, $g_\omega^{q'} = g_b$, where I is the transformation $I[v] = [v]$ for all $[v] \in \mathcal{L}_c$. The irreducible representations of $\tilde{G}_c$ are one-dimensional and can be described in terms of generators as [5]

$$\begin{cases} T_{(\kappa, m)}(g_{c'}) = e^{-i2\pi m/n} \\ T_{(\kappa, m)}(g_\omega) = e^{-i\kappa a/q'} \end{cases} \quad \text{where} \quad \begin{cases} m \in \{0, 1, \dots, n-1\} \\ \kappa \in [0, 2\pi q'/a) \end{cases} \quad (32)$$

The irreducible representations of G_c can be obtained from the irreducible representations of $\tilde{G}_c$ by using the index-two subgroup induction.

Consider the Hilbert space $(l^2(\mathcal{L}_c), \langle, \rangle)$, where

$$l^2(\mathcal{L}_c) = \left\{ \psi : \mathcal{L}_c \longrightarrow \mathbb{C} \left| \sum_{v \in \mathcal{L}_c} |\psi(v)|^2 < \infty \right. \right\}$$

$$\langle \psi_1, \psi_2 \rangle = \sum_{v \in \mathcal{L}_c} \overline{\psi_1(v)} \psi_2(v) \quad (33)$$

and the unitary representation of G_c in $l^2(\mathcal{L}_c)$ defined by

$$g : l^2(\mathcal{L}_c) \longrightarrow l^2(\mathcal{L}_c) \quad (g\psi)[v] = \psi(g^{-1}[v]). \quad (34)$$

If ε is a real number and $\gamma_0, \gamma_1, \gamma_2$ are three complex numbers, then the linear operator

$$H : l^2(\mathcal{L}_c) \longrightarrow l^2(\mathcal{L}_c) \quad (H\psi)[v] = \varepsilon\psi[v] + \sum_{j=0}^2 \gamma(v, v^j) \psi[v^j] \quad (35)$$

with $\gamma(v, v^j)$ defined by (14), is a self-adjoint operator.

Theorem 3. *For any $k = (k_0, k_1, k_2) \in \mathcal{E}$ satisfying the relation*

$$\langle k, c \rangle = k_0 c_0 + k_1 c_1 + k_2 c_2 \in (2\pi/a)\mathbb{Z} \quad (36)$$

the real numbers

$$E_{\pm}(k) = \varepsilon \pm |\gamma_0 e^{ik_0 a} + \gamma_1 e^{ik_1 a} + \gamma_2 e^{ik_2 a}| \quad (37)$$

belong to the spectrum of H .

Proof. For $k \in \mathcal{E}$ satisfying (36) we have

$$v - u \in \mathbb{Z}c \implies \varphi(v) e^{i\langle k, v \rangle a} = \varphi(u) e^{i\langle k, u \rangle a}$$

and hence the Bloch type function

$$\psi_k : \mathcal{L}_c \longrightarrow \mathbb{C} \quad \psi_k[v] = \varphi(v) e^{i\langle k, v \rangle a} \quad (38)$$

is well-defined. If $E \in \{E_+(k), E_-(k)\}$ then there exists a non-null function of this form satisfying the relation $H\psi_k = E\psi_k$. ■

If $\gamma_0, \gamma_1, \gamma_2$ are real then H is G_c -invariant. Indeed, since $g_{c'} v^j = (g_{c'} v)^j$, $g_{\omega} v^j = (g_{\omega} v)^j$ and $\tau v^j = (\tau v)^j$ we have $gHg^{-1} = H$, for any $g \in G_c$. Denoting $\langle k, c \rangle = 2m\pi/a$ and $\langle k, \omega \rangle = \kappa/q'$ we get

$$(g_{c'} \psi_k)[v] = \varphi(v) e^{i\langle k, v - c' \rangle a} = e^{-i\langle k, c' \rangle a} \psi_k[v] = e^{-i2m\pi/n} \psi_k[v]$$

$$(g_\omega \psi_k)[v] = \varphi(v) e^{i\langle k, v-\omega \rangle a} = e^{-i\langle k, \omega \rangle a} \psi_k[v] = e^{-i\kappa a/q'} \psi_k[v] \quad (39)$$

$$(\tau \psi_k)[v] = \varphi(\tau v) e^{i\langle k, -v+\vartheta \rangle a} = (\varphi(\tau v)/\varphi(v)) e^{ik_0 a} \psi_{-k}[v]$$

that is, the subspace generated by ψ_k and ψ_{-k} is G_c -invariant. More than that, these relations allow us [5] to classify the eigenstates ψ_k by using the quantum numbers m and κ . The set (figure 2)

$$\mathcal{B}_c = \left\{ k \in \mathcal{E} \left| \begin{array}{l} \langle k, c \rangle = 2m\pi/a \text{ with } m \in \{0, 1, \dots, n-1\} \\ \langle k, \omega \rangle = \kappa/q' \text{ with } \kappa \in [0, 2q'\pi/a) \end{array} \right. \right\}. \quad (40)$$

contains a k corresponding to each class. The conduction m -band

$$\{E_+(k) \mid \langle k, c \rangle = 2m\pi/a, \langle k, \omega \rangle \in [0, 2\pi q'/a)\} \quad (41)$$

and the valence m -band

$$\{E_-(k) \mid \langle k, c \rangle = 2m\pi/a, \langle k, \omega \rangle \in [0, 2\pi q'/a)\} \quad (42)$$

can easily be determined by using (37). A graphic representation of these conduction bands can be found in [5].

The relation (36) defines a family of equidistant straight lines orthogonal to c with the distance between neighbouring lines equal to $\delta = 2\pi/(a||c||)$. Since the length of the projection of the vector $(2\pi/(3a), -2\pi/(3a), 0)$ on c is $2\pi(c_0 - c_1)/(3a||c||) = (c_0 - c_1)\delta/3$, the K points belong to the straight lines (36) if and only if $c_0 - c_1 \in 3\mathbb{Z}$.

The Hamiltonian used in the tight-binding description of π bands in $\mathcal{L}_c$, with only first-neighbour $C-C$ interaction, has the form (35). Except for very small diameter nanotubes, the constants $\gamma_0, \gamma_1, \gamma_2$ keep almost the same values as in the case of a graphene sheet [1,16]. Neglecting the effects of the curvature of the graphite sheet, we can assume $\varepsilon = 0$, $\gamma_0 = \gamma_1 = \gamma_2 = \gamma \in (0, \infty)$, and we get the energy levels

$$E_\pm(k) = \pm \gamma \sqrt{3 + 2 \cos(k_0 - k_1)a + 2 \cos(k_1 - k_2)a + 2 \cos(k_2 - k_0)a}. \quad (43)$$

From the form of the surface $E(k)$ [12], it follows that the gap between the valence and conduction bands is given by

$$\Delta E_c = \min_{k \in \mathcal{B}_c} E_+(k) - \max_{k \in \mathcal{B}_c} E_-(k) = 2 \min_{k \in \mathcal{B}_c} E(k) \quad (44)$$

and we have $\Delta E_c = 0$ if and only if $c_0 - c_1 \in 3\mathbb{Z}$. Therefore [7,16], the nanotube $\mathcal{L}_c$ is a conductor if $c_0 - c_1 \in 3\mathbb{Z}$, and a semiconductor if $c_0 - c_1 \notin 3\mathbb{Z}$. The minimum $\min_{k \in \mathcal{B}_c} E(k)$ is achieved [12] at a point lying on a straight line (36) in the vicinity of a point K .

In the case of a magnetic field parallel to the nanotube axis the Hamiltonian also has the form (35), but $\gamma_0 = \gamma e^{i\beta c_0 a}$, $\gamma_1 = \gamma e^{i\beta c_1 a}$, $\gamma_2 = \gamma e^{i\beta c_2 a}$, where β is a real constant describing the magnetic field strength threading the nanotube [9]. Choosing $\varepsilon = 0$, $\gamma \in (0, \infty)$, we get the energy levels

$$E_{\pm}^{mag}(k) = \pm \gamma |e^{i(k_0 + \beta c_0)a} + e^{i(k_1 + \beta c_1)a} + e^{i(k_2 + \beta c_2)a}| = E_{\pm}(k + \beta c) \quad (45)$$

for any k satisfying (36). From this relation it follows that the presence of a magnetic field parallel to the nanotube axis can modify drastically the electronic properties of the nanotube, and this modification depends essentially on the nanotube chirality [9].

4 Concluding remarks

The alternate description presented in this paper offers certain formal advantages and is significantly different from the usual one. We think that it can be used as a complementary description, and may stimulate the interest of mathematicians in the fascinating geometry of carbon nanotubes. We have re-obtained some known results [5,6,8,9,11,12,16] concerning the chiral carbon nanotubes in order to illustrate the proposed approach.

Since our model is a factor space, we have to verify the independence of the representative (v_0, v_1, v_2) we choose for $[v_0, v_1, v_2]$ in the case of any mathematical object we consider on $\mathcal{L}_c$. This is not an inconvenience for our approach but a useful criterion when we look for mathematical objects with possible geometric or physical significance .
